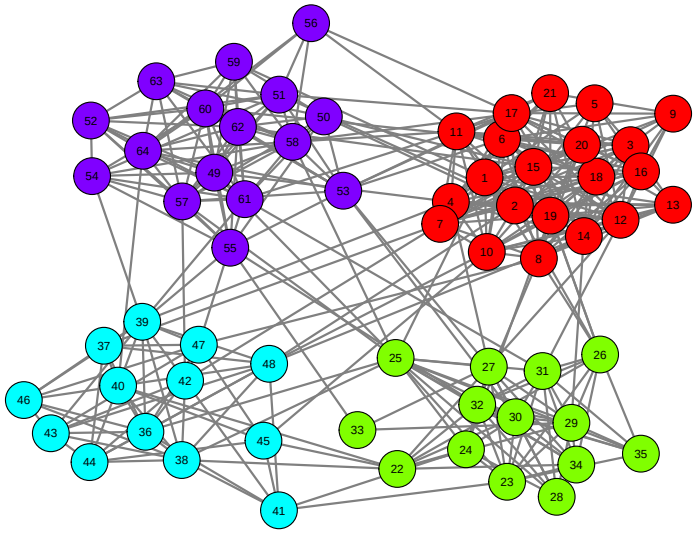
Community Detection for Networks



Def Popularity Adjusted Block Model (Sengupta and Chen, 2017):

Let each vertex $i \in [n]$ have K popularity parameters
$\lambda_{i1}, ..., \lambda_{iK} \in [0, 1]$.
Then $A \sim \text{BernoulliGraph}(P)$ is a PABM if each $P_{ij} = \lambda_{iz_j}\lambda_{jz_i}$

Connecting Block Models to the GRDPG

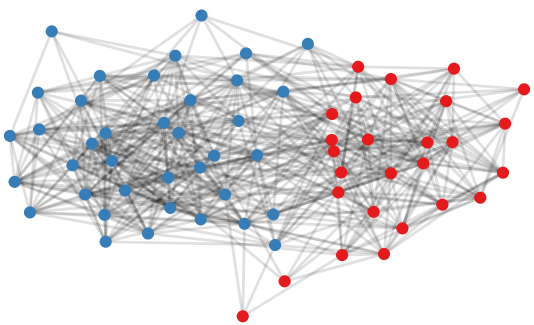
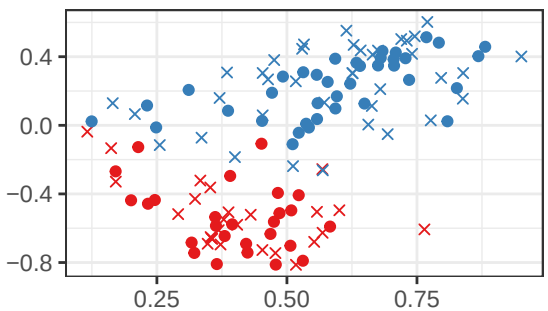
PABM



Subspaces (Projected)



- K-means clustering
- Gaussian mixture models

- K-means with cosine similarity
- GMM on angles

- ???

Orthogonal Spectral Clustering

Theorem (KTT): If $P = V\Lambda V^\top$ and $B = nVV^\top$, then $B_{ij} = 0$ if $z_i \neq z_j$.

Algorithm: Orthogonal Spectral Clustering:

1. Let V be the eigenvectors of A corresponding to the $K(K+1)/2$ most positive and $K(K-1)/2$ most negative eigenvalues.
2. Compute $B = |nVV^\top|$ applying $|\cdot|$ entry-wise.
3. Construct graph G using B as its similarity matrix.
4. Partition G into K disconnected subgraphs.

Theorem (KTT): $\forall$ pairs (i, j) belonging to different communities, $\max_{i,j} B_{ij} = O_P\left(\frac{(\log n)^c}{\sqrt{n\rho_n}}\right)$.

Corollary: OSC results in zero clustering error as $n \to \infty$, with probability 1.
